Chapter 1

Refinement of Literals

1.1 Literals as Natural Numbers

1.1.1 Definition

lemma *Pos-div2-iff*:

$$\langle \text{Pos } ((bb :: \text{nat}) \text{ div } 2) = b \longleftrightarrow \text{is-pos } b \wedge (bb = 2 * \text{atm-of } b \vee bb = 2 * \text{atm-of } b + 1) \rangle$$

<proof>

lemma *Neg-div2-iff*:

$$\langle \text{Neg } ((bb :: \text{nat}) \text{ div } 2) = b \longleftrightarrow \text{is-neg } b \wedge (bb = 2 * \text{atm-of } b \vee bb = 2 * \text{atm-of } b + 1) \rangle$$

<proof>

Modeling *nat literal* via the transformation associating $(2::'a) * n$ or $(2::'a) * n + (1::'a)$ has some advantages over the transformation to positive or negative integers: 0 is not an issue. It is also a bit faster according to Armin Biere.

fun *nat-of-lit* :: $\langle \text{nat literal} \Rightarrow \text{nat} \rangle$ **where**

$$\langle \text{nat-of-lit } (\text{Pos } L) = 2 * L \rangle$$

$$| \langle \text{nat-of-lit } (\text{Neg } L) = 2 * L + 1 \rangle$$

lemma *nat-of-lit-def*: $\langle \text{nat-of-lit } L = (\text{if is-pos } L \text{ then } 2 * \text{atm-of } L \text{ else } 2 * \text{atm-of } L + 1) \rangle$

<proof>

fun *literal-of-nat* :: $\langle \text{nat} \Rightarrow \text{nat literal} \rangle$ **where**

$$\langle \text{literal-of-nat } n = (\text{if even } n \text{ then } \text{Pos } (n \text{ div } 2) \text{ else } \text{Neg } (n \text{ div } 2)) \rangle$$

lemma *lit-of-nat-nat-of-lit[simp]*: $\langle \text{literal-of-nat } (\text{nat-of-lit } L) = L \rangle$

<proof>

lemma *nat-of-lit-lit-of-nat[simp]*: $\langle \text{nat-of-lit } (\text{literal-of-nat } n) = n \rangle$

<proof>

lemma *atm-of-lit-of-nat*: $\langle \text{atm-of } (\text{literal-of-nat } n) = n \text{ div } 2 \rangle$

<proof>

There is probably a more “closed” form from the following theorem, but it is unclear if that is useful or not.

lemma *uminus-lit-of-nat*:

$$\langle - (\text{literal-of-nat } n) = (\text{if even } n \text{ then } \text{literal-of-nat } (n+1) \text{ else } \text{literal-of-nat } (n-1)) \rangle$$

<proof>

lemma *literal-of-nat-literal-of-nat-eq[iff]*: $\langle \text{literal-of-nat } x = \text{literal-of-nat } xa \longleftrightarrow x = xa \rangle$

⟨proof⟩

definition *nat-lit-rel* :: ⟨(nat × nat literal) set⟩ **where**
 ⟨nat-lit-rel = br literal-of-nat (λ-. True)⟩

lemma *ex-literal-of-nat*: ⟨∃ bb. b = literal-of-nat bb⟩
 ⟨proof⟩

1.1.2 Lifting to annotated literals

fun *pair-of-ann-lit* :: ⟨('a, 'b) ann-lit ⇒ 'a literal × 'b option⟩ **where**
 ⟨pair-of-ann-lit (Propagated L D) = (L, Some D)⟩
 | ⟨pair-of-ann-lit (Decided L) = (L, None)⟩

fun *ann-lit-of-pair* :: ⟨'a literal × 'b option ⇒ ('a, 'b) ann-lit⟩ **where**
 ⟨ann-lit-of-pair (L, Some D) = Propagated L D⟩
 | ⟨ann-lit-of-pair (L, None) = Decided L⟩

lemma *ann-lit-of-pair-alt-def*:
 ⟨ann-lit-of-pair (L, D) = (if D = None then Decided L else Propagated L (the D))⟩
 ⟨proof⟩

lemma *ann-lit-of-pair-pair-of-ann-lit*: ⟨ann-lit-of-pair (pair-of-ann-lit L) = L⟩
 ⟨proof⟩

lemma *pair-of-ann-lit-ann-lit-of-pair*: ⟨pair-of-ann-lit (ann-lit-of-pair L) = L⟩
 ⟨proof⟩

lemma *literal-of-neq-eq-nat-of-lit-eq-iff*: ⟨literal-of-nat b = L ⟷ b = nat-of-lit L⟩
 ⟨proof⟩

lemma *nat-of-lit-eq-iff*[iff]: ⟨nat-of-lit xa = nat-of-lit x ⟷ x = xa⟩
 ⟨proof⟩

definition *ann-lit-rel*:: ⟨('a × nat) set ⇒ ('b × nat option) set ⇒
 ((('a × 'b) × (nat, nat) ann-lit) set) **where**
ann-lit-rel-internal-def:
 ⟨ann-lit-rel R R' = {(a, b). ∃ c d. (fst a, c) ∈ R ∧ (snd a, d) ∈ R' ∧
 b = ann-lit-of-pair (literal-of-nat c, d)}⟩

1.2 Conflict Clause

definition *the-is-empty* **where**
 ⟨the-is-empty D = Multiset.is-empty (the D)⟩

1.3 Atoms with bound

definition *uint32-max* :: nat **where**
 ⟨uint32-max ≡ 2³² - 1⟩

definition *uint64-max* :: nat **where**
 ⟨uint64-max ≡ 2⁶⁴ - 1⟩

definition *sint32-max* :: nat **where**
 ⟨sint32-max ≡ 2³¹ - 1⟩

definition *sint64-max* :: *nat* **where**
 $\langle \text{sint64-max} \equiv 2^{63} - 1 \rangle$

lemma *uint64-max-uint-def*: $\langle \text{unat } (-1 :: 64 \text{ Word.word}) = \text{uint64-max} \rangle$
 $\langle \text{proof} \rangle$

1.4 Operations with set of atoms.

context
fixes $\mathcal{A}_{in} :: \langle \text{nat multiset} \rangle$
begin

abbreviation $D_0 :: \langle (\text{nat} \times \text{nat literal}) \text{ set} \rangle$ **where**
 $\langle D_0 \equiv (\lambda L. (\text{nat-of-lit } L, L)) \text{ ' set-mset } (\mathcal{L}_{all} \mathcal{A}_{in}) \rangle$

definition *length-ll-f* **where**
 $\langle \text{length-ll-f } W L = \text{length } (W L) \rangle$

The following lemma was necessary at some point to prove the existence of some list.

lemma *ex-list-watched*:
fixes $W :: \langle \text{nat literal} \Rightarrow 'a \text{ list} \rangle$
shows $\langle \exists aa. \forall x \in \# \mathcal{L}_{all} \mathcal{A}_{in}. \text{nat-of-lit } x < \text{length } aa \wedge aa ! \text{nat-of-lit } x = W x \rangle$
(is $\langle \exists aa. ?P aa \rangle$
 $\langle \text{proof} \rangle$

definition *isasat-input-bounded* **where**
 $\langle \text{simp} \rangle: \langle \text{isasat-input-bounded} = (\forall L \in \# \mathcal{L}_{all} \mathcal{A}_{in}. \text{nat-of-lit } L \leq \text{uint32-max}) \rangle$

definition *isasat-input-empty* **where**
 $\langle \text{simp} \rangle: \langle \text{isasat-input-empty} = (\text{set-mset } \mathcal{A}_{in} \neq \{\}) \rangle$

definition *isasat-input-bounded-empty* **where**
 $\langle \text{isasat-input-bounded-empty} = (\text{isasat-input-bounded} \wedge \text{isasat-input-empty}) \rangle$

1.5 Set of atoms with bound

context
assumes *in- \mathcal{L}_{all} -less-uint32-max*: $\langle \text{isasat-input-bounded} \rangle$
begin

lemma *in- \mathcal{L}_{all} -less-uint32-max'*: $\langle L \in \# \mathcal{L}_{all} \mathcal{A}_{in} \implies \text{nat-of-lit } L \leq \text{uint32-max} \rangle$
 $\langle \text{proof} \rangle$

lemma *in- \mathcal{A}_{in} -less-than-uint32-max-div-2*:

Chapter 2

The memory representation: Arenas

We implement an “arena” memory representation: This is a flat representation of clauses, where all clauses and their headers are put one after the other. A lot of the work done here could be done automatically by a C compiler (see paragraph on Cadical below).

While this has some advantages from a performance point of view compared to an array of arrays, it allows to emulate pointers to the middle of array with extra information put before the pointer. This is an optimisation that is considered as important (at least according to Armin Biere).

In Cadical, the representation is done that way although it is implicit by putting an array into a structure (and rely on UB behaviour to make sure that the array is “inlined” into the structure). Cadical also uses another trick: the array is but inside a union. This union contains either the clause or a pointer to the new position if it has been moved (during GC-ing). There is no way for us to do so in a type-safe manner that works both for *uint64* and *nat* (unless we know some details of the implementation). For *uint64*, we could use the space used by the headers. However, it is not clear if we want to do do, since the behaviour would change between the two types, making a comparison impossible. This means that half of the blocking literals will be lost (if we iterate over the watch lists) or all (if we iterate over the clauses directly).

The order in memory is in the following order:

1. the saved position (was optional in cadical too; since sr-19, not optional);
2. the status and LBD;
3. the size;
4. the clause.

Remark that the information can be compressed to reduce the size in memory:

1. the saved position can be skipped for short clauses;
2. the LBD will most of the time be much shorter than a 32-bit integer, so only an approximation can be kept and the remaining bits be reused for the status;

In previous iteration, we had something a bit simpler:

1. the LBD was in a separate field, allowing to store the complete LBD (which does not matter).

2. the activity was also stored and used for ties. This was beneficial on some problems (including the *eq.atree.braun* problems), but we later decided to remove it to consume less memory. This did not make a difference on the overall benchmark set. For ties, we use a pure MTF-like scheme and keep newer clauses (like CaDiCaL).

In our case, the refinement is done in two steps:

1. First, we refine our clause-mapping to a big list. This list contains the original elements. For type safety, we introduce a datatype that enumerates all possible kind of elements.
2. Then, we refine all these elements to uint32 elements.

In our formalisation, we distinguish active clauses (clauses that are not marked to be deleted) from dead clauses (that have been marked to be deleted but can still be accessed). Any dead clause can be removed from the addressable clauses (*vdom* for virtual domain). Remark that we actually do not need the full virtual domain, just the list of all active position (TODO?).

Remark that in our formalisation, we don't (at least not yet) plan to reuse freed spaces (the predicate about dead clauses must be strengthened to do so). Due to the fact that an arena is very different from an array of clauses, we refine our data structure by hand to the long list instead of introducing refinement rules. This is mostly done because iteration is very different (and it does not change what we had before anyway).

Some technical details: due to the fact that we plan to refine the arena to uint32 and that our clauses can be tautologies, the size does not fit into uint32 (technically, we have the bound $\text{uint32-max} + 1$). Therefore, we restrict the clauses to have at least length 2 and we keep $\text{length } C - 2$ instead of $\text{length } C$ (same for position saving). If we ever add a preprocessing path that removes tautologies, we could get rid of these two limitations.

To our own surprise, using an arena (without position saving) was exactly as fast as the our former resizable array of arrays. We did not expect this result since:

1. First, we cannot use *uint32* to iterate over clauses anymore (at least no without an additional trick like considering a slice).
2. Second, there is no reason why MLton would not already use the trick for array.

(We assume that there is no gain due the order in which we iterate over clauses, which seems a reasonable assumption, even when considering than some clauses will subsume the previous one, and therefore, have a high chance to be in the same watch lists).

We can mark clause as used. This trick is used to implement a MTF-like scheme to keep clauses.

2.1 Status of a clause

datatype *clause-status* = *IRRED* | *LEARNED* | *DELETED*

instantiation *clause-status* :: *default*
begin

definition *default-clause-status* **where** $\langle \text{default-clause-status} = \text{DELETED} \rangle$

instance $\langle \text{proof} \rangle$

end

2.2 Definition

The following definitions are the offset between the beginning of the clause and the specific headers before the beginning of the clause. Remark that the first offset is not always valid. Also remark that the fields are *before* the actual content of the clause.

definition *POS-SHIFT* :: *nat* **where**
 $\langle \text{POS-SHIFT} = 3 \rangle$

definition *STATUS-SHIFT* :: *nat* **where**
 $\langle \text{STATUS-SHIFT} = 2 \rangle$

abbreviation *LBD-SHIFT* :: *nat* **where**
 $\langle \text{LBD-SHIFT} \equiv \text{STATUS-SHIFT} \rangle$

lemmas *LBD-SHIFT-def* = *STATUS-SHIFT-def*

definition *SIZE-SHIFT* :: *nat* **where**
 $\langle \text{SIZE-SHIFT} = 1 \rangle$

definition *MAX-LENGTH-SHORT-CLAUSE* :: *nat* **where**
 $\langle \text{simp} \rangle: \langle \text{MAX-LENGTH-SHORT-CLAUSE} = 4 \rangle$

definition *is-short-clause* **where**
 $\langle \text{simp} \rangle: \langle \text{is-short-clause } C \longleftrightarrow \text{length } C \leq \text{MAX-LENGTH-SHORT-CLAUSE} \rangle$

abbreviation *is-long-clause* **where**
 $\langle \text{is-long-clause } C \equiv \neg \text{is-short-clause } C \rangle$

abbreviation (*input*) *MAX-HEADER-SIZE* :: *nat* **where**
 $\langle \text{MAX-HEADER-SIZE} \equiv 3 \rangle$

abbreviation (*input*) *MIN-HEADER-SIZE* :: *nat* **where**
 $\langle \text{MIN-HEADER-SIZE} \equiv 2 \rangle$

definition *header-size* :: *nat clause-l* \Rightarrow *nat* **where**
 $\langle \text{header-size } C = (\text{if is-short-clause } C \text{ then MIN-HEADER-SIZE else MAX-HEADER-SIZE}) \rangle$

lemmas *SHIFTS-def* = *POS-SHIFT-def* *STATUS-SHIFT-def* *SIZE-SHIFT-def*

In an attempt to avoid unfolding definitions and to not rely on the actual value of the positions of the headers before the clauses.

lemma *arena-shift-distinct*:

$\langle i > \text{MIN-HEADER-SIZE} \Rightarrow i - \text{SIZE-SHIFT} \neq i - \text{LBD-SHIFT} \rangle$
 $\langle i > \text{MIN-HEADER-SIZE} \Rightarrow i - \text{SIZE-SHIFT} \neq i - \text{STATUS-SHIFT} \rangle$
 $\langle i > \text{MAX-HEADER-SIZE} \Rightarrow i - \text{SIZE-SHIFT} \neq i - \text{POS-SHIFT} \rangle$
 $\langle i > \text{MAX-HEADER-SIZE} \Rightarrow i - \text{LBD-SHIFT} \neq i - \text{POS-SHIFT} \rangle$
 $\langle i > \text{MAX-HEADER-SIZE} \Rightarrow i - \text{STATUS-SHIFT} \neq i - \text{POS-SHIFT} \rangle$
 $\langle i > \text{MIN-HEADER-SIZE} \Rightarrow j > \text{MIN-HEADER-SIZE} \Rightarrow i - \text{SIZE-SHIFT} = j - \text{SIZE-SHIFT} \longleftrightarrow i = j \rangle$
 $\langle i > \text{MIN-HEADER-SIZE} \Rightarrow j > \text{MIN-HEADER-SIZE} \Rightarrow i - \text{LBD-SHIFT} = j - \text{LBD-SHIFT} \longleftrightarrow i = j \rangle$
 $\langle i > \text{MIN-HEADER-SIZE} \Rightarrow j > \text{MIN-HEADER-SIZE} \Rightarrow i - \text{STATUS-SHIFT} = j - \text{STATUS-SHIFT} \longleftrightarrow i = j \rangle$

$\langle i > \text{MAX-HEADER-SIZE} \implies j > \text{MAX-HEADER-SIZE} \implies i - \text{POS-SHIFT} = j - \text{POS-SHIFT} \longleftrightarrow i = j \rangle$

$\langle i \geq \text{header-size } C \implies i - \text{SIZE-SHIFT} \neq i - \text{LBD-SHIFT} \rangle$
 $\langle i \geq \text{header-size } C \implies i - \text{SIZE-SHIFT} \neq i - \text{STATUS-SHIFT} \rangle$

 $\langle \text{proof} \rangle$

lemma *header-size-ge0[simp]*: $\langle 0 < \text{header-size } x1 \rangle$
 $\langle \text{proof} \rangle$

datatype *arena-el* =
is-Lit: *ALit* (*xarena-lit*: $\langle \text{nat literal} \rangle$) |
is-Size: *ASize* (*xarena-length*: *nat*) |
is-Pos: *APos* (*xarena-pos*: *nat*) |
is-Status: *AStatus* (*xarena-status*: *clause-status*) (*xarena-used*: *nat*) (*xarena-lbd*: *nat*)

type-synonym *arena* = $\langle \text{arena-el list} \rangle$

definition *xarena-active-clause* :: $\langle \text{arena} \Rightarrow \text{nat clause-l} \times \text{bool} \Rightarrow \text{bool} \rangle$ **where**
 $\langle \text{xarena-active-clause arena} = (\lambda(C, \text{red}).$
 $(\text{length } C \geq 2 \wedge$
 $\text{header-size } C + \text{length } C = \text{length arena} \wedge$
 $(\text{is-long-clause } C \longrightarrow (\text{is-Pos } (\text{arena}!(\text{header-size } C - \text{POS-SHIFT}))) \wedge$
 $\text{xarena-pos}(\text{arena}!(\text{header-size } C - \text{POS-SHIFT})) \leq \text{length } C - 2))) \wedge$
 $\text{is-Status}(\text{arena}!(\text{header-size } C - \text{STATUS-SHIFT})) \wedge$
 $(\text{xarena-status}(\text{arena}!(\text{header-size } C - \text{STATUS-SHIFT})) = \text{IRRED} \longleftrightarrow \text{red}) \wedge$
 $(\text{xarena-status}(\text{arena}!(\text{header-size } C - \text{STATUS-SHIFT})) = \text{LEARNED} \longleftrightarrow \neg \text{red}) \wedge$
 $\text{is-Size}(\text{arena}!(\text{header-size } C - \text{SIZE-SHIFT})) \wedge$
 $\text{xarena-length}(\text{arena}!(\text{header-size } C - \text{SIZE-SHIFT})) + 2 = \text{length } C \wedge$
 $\text{drop } (\text{header-size } C) \text{ arena} = \text{map } \text{ALit } C$
 \rangle

As $(N \propto i, \text{irred } N i)$ is automatically simplified to *the* $(\text{fmlookup } N i)$, we provide an alternative definition that uses the result after the simplification.

lemma *xarena-active-clause-alt-def*:
 $\langle \text{xarena-active-clause arena } (\text{the } (\text{fmlookup } N i)) \longleftrightarrow ($
 $(\text{length } (N \propto i) \geq 2 \wedge$
 $\text{header-size } (N \propto i) + \text{length } (N \propto i) = \text{length arena} \wedge$
 $(\text{is-long-clause } (N \propto i) \longrightarrow (\text{is-Pos } (\text{arena}!(\text{header-size } (N \propto i) - \text{POS-SHIFT}))) \wedge$
 $\text{xarena-pos}(\text{arena}!(\text{header-size } (N \propto i) - \text{POS-SHIFT})) \leq \text{length } (N \propto i) - 2))) \wedge$
 $\text{is-Status}(\text{arena}!(\text{header-size } (N \propto i) - \text{STATUS-SHIFT})) \wedge$
 $(\text{xarena-status}(\text{arena}!(\text{header-size } (N \propto i) - \text{STATUS-SHIFT})) = \text{IRRED} \longleftrightarrow \text{irred } N i) \wedge$
 $(\text{xarena-status}(\text{arena}!(\text{header-size } (N \propto i) - \text{STATUS-SHIFT})) = \text{LEARNED} \longleftrightarrow \neg \text{irred } N i) \wedge$
 $\text{is-Size}(\text{arena}!(\text{header-size } (N \propto i) - \text{SIZE-SHIFT})) \wedge$
 $\text{xarena-length}(\text{arena}!(\text{header-size } (N \propto i) - \text{SIZE-SHIFT})) + 2 = \text{length } (N \propto i) \wedge$
 \rangle

$\text{drop } (\text{header-size } (N \times i)) \text{ arena} = \text{map } \text{ALit } (N \times i)$
 $\rangle\rangle\rangle$
 $\langle \text{proof} \rangle$

The extra information is required to prove “separation” between active and dead clauses. And it is true anyway and does not require any extra work to prove. TODO generalise LBD to extract from every clause?

definition *arena-dead-clause* :: $\langle \text{arena} \Rightarrow \text{bool} \rangle$ **where**
 $\langle \text{arena-dead-clause arena} \longleftrightarrow$
 $\text{is-Status}(\text{arena}!(\text{MIN-HEADER-SIZE} - \text{STATUS-SHIFT})) \wedge \text{xarena-status}(\text{arena}!(\text{MIN-HEADER-SIZE}$
 $- \text{STATUS-SHIFT})) = \text{DELETED} \wedge$
 $\text{is-Size}(\text{arena}!(\text{MIN-HEADER-SIZE} - \text{SIZE-SHIFT}))$
 \rangle

When marking a clause as garbage, we do not care whether it was used or not.

definition *extra-information-mark-to-delete* **where**
 $\langle \text{extra-information-mark-to-delete arena } i = \text{arena}[i - \text{STATUS-SHIFT} := \text{AStatus DELETED } 0 \ 0] \rangle$

This extracts a single clause from the complete arena.

abbreviation *clause-slice* **where**
 $\langle \text{clause-slice arena } N \ i \equiv \text{Misc.slice } (i - \text{header-size } (N \times i)) \ (i + \text{length}(N \times i)) \text{ arena} \rangle$

abbreviation *dead-clause-slice* **where**
 $\langle \text{dead-clause-slice arena } N \ i \equiv \text{Misc.slice } (i - \text{MIN-HEADER-SIZE}) \ i \text{ arena} \rangle$

We now can lift the validity of the active and dead clauses to the whole memory and link it the mapping to clauses and the addressable space.

In our first try, the predicated *xarena-active-clause* took the whole arena as parameter. This however turned out to make the proof about updates less modular, since the slicing already takes care to ignore all irrelevant changes.

definition *valid-arena* :: $\langle \text{arena} \Rightarrow \text{nat clauses-l} \Rightarrow \text{nat set} \Rightarrow \text{bool} \rangle$ **where**
 $\langle \text{valid-arena arena } N \ \text{vdom} \longleftrightarrow$
 $(\forall i \in \# \text{ dom-m } N. \ i < \text{length arena} \wedge i \geq \text{header-size } (N \times i) \wedge$
 $\text{xarena-active-clause } (\text{clause-slice arena } N \ i) \ (\text{the } (\text{fmlookup } N \ i))) \wedge$
 $(\forall i \in \text{vdom}. \ i \notin \# \text{ dom-m } N \longrightarrow (i < \text{length arena} \wedge i \geq \text{MIN-HEADER-SIZE} \wedge$
 $\text{arena-dead-clause } (\text{dead-clause-slice arena } N \ i)))$
 \rangle

lemma *valid-arena-empty*: $\langle \text{valid-arena } [] \ \text{fmempty } \{\} \rangle$
 $\langle \text{proof} \rangle$

definition *arena-status* **where**
 $\langle \text{arena-status arena } i = \text{xarena-status } (\text{arena}!(i - \text{STATUS-SHIFT})) \rangle$

definition *arena-used* **where**
 $\langle \text{arena-used arena } i = \text{xarena-used } (\text{arena}!(i - \text{STATUS-SHIFT})) \rangle$

definition *arena-length* **where**
 $\langle \text{arena-length arena } i = 2 + \text{xarena-length } (\text{arena}!(i - \text{SIZE-SHIFT})) \rangle$

definition *arena-lbd* **where**
 $\langle \text{arena-lbd arena } i = \text{xarena-lbd } (\text{arena}!(i - \text{LBD-SHIFT})) \rangle$

definition *arena-pos* **where**

$\langle \text{arena-pos arena } i = 2 + \text{xarena-pos (arena!}(i - \text{POS-SHIFT})) \rangle$

definition *arena-lit* **where**

$\langle \text{arena-lit arena } i = \text{xarena-lit (arena!}i) \rangle$

2.3 Separation properties

The following two lemmas talk about the minimal distance between two clauses in memory. They are important for the proof of correctness of all update function.

lemma *minimal-difference-between-valid-index:*

assumes $\langle \forall i \in \# \text{ dom-m } N. i < \text{length arena} \wedge i \geq \text{header-size } (N \times i) \wedge$
 $\text{xarena-active-clause (clause-slice arena } N \text{ } i) \text{ (the (fmlookup } N \text{ } i))} \rangle$ **and**

$\langle i \in \# \text{ dom-m } N \rangle$ **and** $\langle j \in \# \text{ dom-m } N \rangle$ **and** $\langle j > i \rangle$

shows $\langle j - i \geq \text{length } (N \times i) + \text{header-size } (N \times j) \rangle$

$\langle \text{proof} \rangle$

lemma *minimal-difference-between-invalid-index:*

assumes $\langle \text{valid-arena arena } N \text{ vdom} \rangle$ **and**

$\langle i \in \# \text{ dom-m } N \rangle$ **and** $\langle j \notin \# \text{ dom-m } N \rangle$ **and** $\langle j \geq i \rangle$ **and** $\langle j \in \text{vdom} \rangle$

shows $\langle j - i \geq \text{length } (N \times i) + \text{MIN-HEADER-SIZE} \rangle$

$\langle \text{proof} \rangle$

At first we had the weaker $(1::'a) \leq i - j$ which we replaced by $(4::'a) \leq i - j$. The former however was able to solve many more goals due to different handling between $1::'a$ (which is simplified to $\text{Suc } 0$) and $4::'a$ (whi::natch is not). Therefore, we replaced $4::'a$ by $\text{Suc } (\text{Suc } (\text{Suc } 0))$

lemma *minimal-difference-between-invalid-index2:*

assumes $\langle \text{valid-arena arena } N \text{ vdom} \rangle$ **and**

$\langle i \in \# \text{ dom-m } N \rangle$ **and** $\langle j \notin \# \text{ dom-m } N \rangle$ **and** $\langle j < i \rangle$ **and** $\langle j \in \text{vdom} \rangle$

shows $\langle i - j \geq (\text{Suc } (\text{Suc } 0)) \rangle$ **and**

$\langle \text{is-long-clause } (N \times i) \implies i - j \geq (\text{Suc } (\text{Suc } (\text{Suc } 0))) \rangle$

$\langle \text{proof} \rangle$

lemma *valid-arena-in-vdom-le-arena:*

assumes $\langle \text{valid-arena arena } N \text{ vdom} \rangle$ **and** $\langle j \in \text{vdom} \rangle$

shows $\langle j < \text{length arena} \rangle$ **and** $\langle j \geq \text{MIN-HEADER-SIZE} \rangle$

$\langle \text{proof} \rangle$

lemma *valid-minimal-difference-between-valid-index:*

assumes $\langle \text{valid-arena arena } N \text{ vdom} \rangle$ **and**

$\langle i \in \# \text{ dom-m } N \rangle$ **and** $\langle j \in \# \text{ dom-m } N \rangle$ **and** $\langle j > i \rangle$

shows $\langle j - i \geq \text{length } (N \times i) + \text{header-size } (N \times j) \rangle$

$\langle \text{proof} \rangle$

Updates

Mark to delete **lemma** *clause-slice-extra-information-mark-to-delete:*

Preconditions and Assertions for the refinement

The following lemma expresses the relation between the arena and the clauses and especially shows the preconditions to be able to generate code.

The conditions on *arena-status* are in the direction to simplify proofs: If we would try to go in the opposite direction, we could rewrite $\neg \text{irred } N \ i$ into *arena-status arena i* $\neq \text{LEARNED}$, which is a weaker property.

The inequality on the length are here to enable simp to prove inequalities *Suc 0* $<$ *arena-length arena C* automatically. Normally the arithmetic part can prove it from $2 \leq \text{arena-length arena } C$, but as this inequality is simplified away, it does not work.

lemma *arena-lifting*:

assumes *valid*: $\langle \text{valid-arena arena } N \text{ vdom} \rangle$ **and**

i: $\langle i \in \# \text{ dom-}m \ N \rangle$

shows

$\langle i \geq \text{header-size } (N \propto i) \rangle$ **and**

$\langle i < \text{length arena} \rangle$

$\langle \text{is-Size } (\text{arena} ! (i - \text{SIZE-SHIFT})) \rangle$

$\langle \text{length } (N \propto i) = \text{arena-length arena } i \rangle$

$\langle j < \text{length } (N \propto i) \Rightarrow N \propto i ! j = \text{arena-lit arena } (i + j) \rangle$ **and**

$\langle j < \text{length } (N \propto i) \Rightarrow \text{is-Lit } (\text{arena} ! (i+j)) \rangle$ **and**

$\langle j < \text{length } (N \propto i) \Rightarrow i + j < \text{length arena} \rangle$ **and**

$\langle N \propto i ! 0 = \text{arena-lit arena } i \rangle$ **and**

$\langle \text{is-Lit } (\text{arena} ! i) \rangle$ **and**

$\langle i + \text{length } (N \propto i) \leq \text{length arena} \rangle$ **and**

$\langle \text{is-long-clause } (N \propto i) \Rightarrow \text{is-Pos } (\text{arena} ! (i - \text{POS-SHIFT})) \rangle$ **and**

$\langle \text{is-long-clause } (N \propto i) \Rightarrow \text{arena-pos arena } i \leq \text{arena-length arena } i \rangle$ **and**

$\langle \text{True} \rangle$ **and**

$\langle \text{is-Status } (\text{arena} ! (i - \text{STATUS-SHIFT})) \rangle$ **and**

$\langle \text{SIZE-SHIFT} \leq i \rangle$ **and**

$\langle \text{LBD-SHIFT} \leq i \rangle$

$\langle \text{True} \rangle$ **and**

$\langle \text{arena-length arena } i \geq 2 \rangle$ **and**

$\langle \text{arena-length arena } i \geq \text{Suc } 0 \rangle$ **and**

$\langle \text{arena-length arena } i \geq 0 \rangle$ **and**

$\langle \text{arena-length arena } i > \text{Suc } 0 \rangle$ **and**

$\langle \text{arena-length arena } i > 0 \rangle$ **and**

$\langle \text{arena-status arena } i = \text{LEARNED} \longleftrightarrow \neg \text{irred } N \ i \rangle$ **and**

$\langle \text{arena-status arena } i = \text{IRRED} \longleftrightarrow \text{irred } N \ i \rangle$ **and**

$\langle \text{arena-status arena } i \neq \text{DELETED} \rangle$ and
 $\langle \text{Misc.slice } i \ (i + \text{arena-length arena } i) \ \text{arena} = \text{map ALit } (N \propto i) \rangle$
 $\langle \text{proof} \rangle$

lemma *arena-dom-status-iff*:

assumes *valid*: $\langle \text{valid-arena arena } N \ \text{vdom} \rangle$ and

i: $\langle i \in \text{vdom} \rangle$

shows

$\langle i \in \# \text{ dom-m } N \longleftrightarrow \text{arena-status arena } i \neq \text{DELETED} \rangle$ (**is** $\langle ?eq \rangle$ **is** $\langle ?A \longleftrightarrow ?B \rangle$) and
 $\langle \text{is-Status } (\text{arena } ! \ (i - \text{STATUS-SHIFT})) \rangle$ (**is** $\langle ?stat \rangle$) and
 $\langle \text{MIN-HEADER-SIZE} \leq i \rangle$ (**is** $\langle ?ge \rangle$)

$\langle \text{proof} \rangle$

lemma *valid-arena-one-notin-vdomD*:

$\langle \text{valid-arena } M \ N \ \text{vdom} \implies \text{Suc } 0 \notin \text{vdom} \rangle$

$\langle \text{proof} \rangle$

This is supposed to be used as for assertions. There might be a more “local” way to define it, without the need for an existentially quantified clause set. However, I did not find a definition which was really much more useful and more practical.

definition *arena-is-valid-clause-idx* :: $\langle \text{arena} \Rightarrow \text{nat} \Rightarrow \text{bool} \rangle$ **where**

$\langle \text{arena-is-valid-clause-idx arena } i \longleftrightarrow$
 $(\exists N \ \text{vdom}. \text{valid-arena arena } N \ \text{vdom} \wedge i \in \# \text{ dom-m } N) \rangle$

This precondition has weaker preconditions is restricted to extracting the status (the other headers can be extracted but only garbage is returned).

definition *arena-is-valid-clause-vdom* :: $\langle \text{arena} \Rightarrow \text{nat} \Rightarrow \text{bool} \rangle$ **where**

$\langle \text{arena-is-valid-clause-vdom arena } i \longleftrightarrow$
 $(\exists N \ \text{vdom}. \text{valid-arena arena } N \ \text{vdom} \wedge (i \in \text{vdom} \vee i \in \# \text{ dom-m } N)) \rangle$

lemma *SHIFTS-alt-def*:

$\langle \text{POS-SHIFT} = (\text{Suc } (\text{Suc } (\text{Suc } 0))) \rangle$

$\langle \text{STATUS-SHIFT} = (\text{Suc } (\text{Suc } 0)) \rangle$

$\langle \text{SIZE-SHIFT} = \text{Suc } 0 \rangle$

$\langle \text{proof} \rangle$

definition *arena-is-valid-clause-idx-and-access* :: $\langle \text{arena} \Rightarrow \text{nat} \Rightarrow \text{nat} \Rightarrow \text{bool} \rangle$ **where**

$\langle \text{arena-is-valid-clause-idx-and-access arena } i \ j \longleftrightarrow$
 $(\exists N \ \text{vdom}. \text{valid-arena arena } N \ \text{vdom} \wedge i \in \# \text{ dom-m } N \wedge j < \text{length } (N \propto i)) \rangle$

This is the precondition for direct memory access: $N ! i$ where $i = j + (j - i)$ instead of $N \propto j ! (i - j)$.

definition *arena-lit-pre* **where**

Chapter 4

Efficient Trail

Our trail contains several additional information compared to the simple trail:

- the (reversed) trail in an array (i.e., the trail in the same order as presented in “Automated Reasoning”);
- the mapping from any *literal* (and not an atom) to its polarity;
- the mapping from a *atom* to its level or reason (in two different arrays);
- the current level of the state;
- the control stack.

We copied the idea from the mapping from a literals to it polarity instead of an atom to its polarity from a comment by Armin Biere in CaDiCal. We only observed a (at best) faint performance increase, but as it seemed slightly faster and does not increase the length of the formalisation, we kept it.

The control stack is the latest addition: it contains the positions of the decisions in the trail. It is mostly to enable fast restarts (since it allows to directly iterate over all decision of the trail), but might also slightly speed up backjumping (since we know how far we are going back in the trail). Remark that the control stack contains is not updated during the backjumping, but only *after* doing it (as we keep only the the beginning of it).

4.1 Polarities

type-synonym *tri-bool* = $\langle \text{bool option} \rangle$

definition *UNSET* :: $\langle \text{tri-bool} \rangle$ **where**
[simp]: $\langle \text{UNSET} = \text{None} \rangle$

definition *SET-FALSE* :: $\langle \text{tri-bool} \rangle$ **where**
[simp]: $\langle \text{SET-FALSE} = \text{Some False} \rangle$

definition *SET-TRUE* :: $\langle \text{tri-bool} \rangle$ **where**
[simp]: $\langle \text{SET-TRUE} = \text{Some True} \rangle$

definition (in $-$) *tri-bool-eq* :: $\langle \text{tri-bool} \Rightarrow \text{tri-bool} \Rightarrow \text{bool} \rangle$ **where**
 $\langle \text{tri-bool-eq} = (=) \rangle$

4.2 Types

type-synonym *trail-pol* =
 $\langle \text{nat literal list} \times \text{tri-bool list} \times \text{nat list} \times \text{nat list} \times \text{nat} \times \text{nat list} \rangle$

definition *get-level-atm* **where**
 $\langle \text{get-level-atm } M \ L = \text{get-level } M \ (\text{Pos } L) \rangle$

definition *polarity-atm* **where**
 $\langle \text{polarity-atm } M \ L =$
 $\quad (\text{if } \text{Pos } L \in \text{lits-of-l } M \text{ then SET-TRUE}$
 $\quad \text{else if } \text{Neg } L \in \text{lits-of-l } M \text{ then SET-FALSE}$
 $\quad \text{else None}) \rangle$

definition *defined-atm* :: $\langle ('v, \text{nat}) \text{ ann-lits} \Rightarrow 'v \Rightarrow \text{bool} \rangle$ **where**
 $\langle \text{defined-atm } M \ L = \text{defined-lit } M \ (\text{Pos } L) \rangle$

abbreviation *undefined-atm* **where**
 $\langle \text{undefined-atm } M \ L \equiv \neg \text{defined-atm } M \ L \rangle$

4.3 Control Stack

inductive *control-stack* **where**
empty:
 $\langle \text{control-stack } [] \rangle \mid$
cons-prop:
 $\langle \text{control-stack } cs \ M \Longrightarrow \text{control-stack } cs \ (\text{Propagated } L \ C \ \# \ M) \rangle \mid$
cons-dec:
 $\langle \text{control-stack } cs \ M \Longrightarrow n = \text{length } M \Longrightarrow \text{control-stack } (cs \ @ \ [n]) \ (\text{Decided } L \ \# \ M) \rangle$

inductive-cases *control-stackE*: $\langle \text{control-stack } cs \ M \rangle$

lemma *control-stack-length-count-dec*:
 $\langle \text{control-stack } cs \ M \Longrightarrow \text{length } cs = \text{count-decided } M \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-le-length-M*:
 $\langle \text{control-stack } cs \ M \Longrightarrow c \in \text{set } cs \Longrightarrow c < \text{length } M \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-propa[simp]*:
 $\langle \text{control-stack } cs \ (\text{Propagated } x21 \ x22 \ \# \ list) \longleftrightarrow \text{control-stack } cs \ list \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-filter-map-nth*:
 $\langle \text{control-stack } cs \ M \Longrightarrow \text{filter is-decided } (\text{rev } M) = \text{map } (\text{nth } (\text{rev } M)) \ cs \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-empty-cs[simp]*: $\langle \text{control-stack } [] \ M \longleftrightarrow \text{count-decided } M = 0 \rangle$
 $\langle \text{proof} \rangle$

This is an other possible definition. It is not inductive, which makes it easier to reason about appending (or removing) some literals from the trail. It is however much less clear if the definition is correct.

definition *control-stack'* **where**

$\langle \text{control-stack}' cs M \longleftrightarrow$
 $(\text{length } cs = \text{count-decided } M \wedge$
 $(\forall L \in \text{set } M. \text{is-decided } L \longrightarrow (cs ! (\text{get-level } M (\text{lit-of } L) - 1) < \text{length } M \wedge$
 $\text{rev } M!(cs ! (\text{get-level } M (\text{lit-of } L) - 1)) = L))) \rangle$

lemma *control-stack-rev-get-lev:*

$\langle \text{control-stack } cs M \implies$
 $\text{no-dup } M \implies L \in \text{set } M \implies \text{is-decided } L \implies \text{rev } M!(cs ! (\text{get-level } M (\text{lit-of } L) - 1)) = L \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-alt-def-imp:*

$\langle \text{no-dup } M \implies (\bigwedge L. L \in \text{set } M \implies \text{is-decided } L \implies cs ! (\text{get-level } M (\text{lit-of } L) - 1) < \text{length } M \wedge$
 $\text{rev } M!(cs ! (\text{get-level } M (\text{lit-of } L) - 1)) = L) \implies$
 $\text{length } cs = \text{count-decided } M \implies$
 $\text{control-stack } cs M \rangle$
 $\langle \text{proof} \rangle$

lemma *control-stack-alt-def:* $\langle \text{no-dup } M \implies \text{control-stack}' cs M \longleftrightarrow \text{control-stack } cs M \rangle$

$\langle \text{proof} \rangle$

lemma *control-stack-decomp:*

assumes
 $\text{decomp}: \langle (\text{Decided } L \# M1, M2) \in \text{set } (\text{get-all-ann-decomposition } M) \rangle$ **and**
 $cs: \langle \text{control-stack } cs M \rangle$ **and**
 $n-d: \langle \text{no-dup } M \rangle$
shows $\langle \text{control-stack } (\text{take } (\text{count-decided } M1) cs) M1 \rangle$
 $\langle \text{proof} \rangle$

4.4 Encoding of the reasons

definition *DECISION-REASON* :: *nat* **where**

$\langle \text{DECISION-REASON} = 1 \rangle$

definition *ann-lits-split-reasons* **where**

$\langle \text{ann-lits-split-reasons } \mathcal{A} = \{((M, \text{reasons}), M'). M = \text{map lit-of } (\text{rev } M') \wedge$
 $(\forall L \in \text{set } M'. \text{is-proped } L \longrightarrow$
 $\text{reasons} ! (\text{atm-of } (\text{lit-of } L)) = \text{mark-of } L \wedge \text{mark-of } L \neq \text{DECISION-REASON}) \wedge$
 $(\forall L \in \text{set } M'. \text{is-decided } L \longrightarrow \text{reasons} ! (\text{atm-of } (\text{lit-of } L)) = \text{DECISION-REASON}) \wedge$
 $(\forall L \in \# \mathcal{L}_{\text{all}} \mathcal{A}. \text{atm-of } L < \text{length } \text{reasons})$
 $\} \rangle$

definition *trail-pol* :: $\langle \text{nat multiset} \Rightarrow (\text{trail-pol} \times (\text{nat}, \text{nat}) \text{ann-lits}) \text{set} \rangle$ **where**

$\langle \text{trail-pol } \mathcal{A} =$
 $\{((M', xs, lvs, \text{reasons}, k, cs), M). ((M', \text{reasons}), M) \in \text{ann-lits-split-reasons } \mathcal{A} \wedge$
 $\text{no-dup } M \wedge$
 $(\forall L \in \# \mathcal{L}_{\text{all}} \mathcal{A}. \text{nat-of-lit } L < \text{length } xs \wedge xs ! (\text{nat-of-lit } L) = \text{polarity } M L) \wedge$
 $(\forall L \in \# \mathcal{L}_{\text{all}} \mathcal{A}. \text{atm-of } L < \text{length } lvs \wedge lvs ! (\text{atm-of } L) = \text{get-level } M L) \wedge$
 $k = \text{count-decided } M \wedge$
 $(\forall L \in \text{set } M. \text{lit-of } L \in \# \mathcal{L}_{\text{all}} \mathcal{A}) \wedge$
 $\text{control-stack } cs M \wedge$
 $\text{isasat-input-bounded } \mathcal{A} \} \rangle$

4.5 Definition of the full trail

lemma *trail-pol-alt-def:*

$\langle \text{trail-pol } \mathcal{A} = \{((M', xs, lvs, reasons, k, cs), M).$
 $((M', reasons), M) \in \text{ann-lits-split-reasons } \mathcal{A} \wedge$
 $\text{no-dup } M \wedge$
 $(\forall L \in \# \mathcal{L}_{all} \mathcal{A}. \text{nat-of-lit } L < \text{length } xs \wedge xs ! (\text{nat-of-lit } L) = \text{polarity } M L) \wedge$
 $(\forall L \in \# \mathcal{L}_{all} \mathcal{A}. \text{atm-of } L < \text{length } lvs \wedge lvs ! (\text{atm-of } L) = \text{get-level } M L) \wedge$
 $k = \text{count-decided } M \wedge$
 $(\forall L \in \text{set } M. \text{lit-of } L \in \# \mathcal{L}_{all} \mathcal{A}) \wedge$
 $\text{control-stack } cs M \wedge \text{literals-are-in-}\mathcal{L}_{in}\text{-trail } \mathcal{A} M \wedge$
 $\text{length } M < \text{uint32-max} \wedge$
 $\text{length } M \leq \text{uint32-max} \text{ div } 2 + 1 \wedge$
 $\text{count-decided } M < \text{uint32-max} \wedge$
 $\text{length } M' = \text{length } M \wedge$
 $M' = \text{map lit-of } (\text{rev } M) \wedge$
 $\text{isasat-input-bounded } \mathcal{A}$
 \rangle
 $\langle \text{proof} \rangle$

4.6 Code generation

4.6.1 Conversion between incomplete and complete mode

definition $\text{trail-fast-of-slow} :: \langle (\text{nat}, \text{nat}) \text{ ann-lits} \Rightarrow (\text{nat}, \text{nat}) \text{ ann-lits} \rangle$ **where**

4.6.9 Reasons

definition *get-propagation-reason-pol* :: $\langle \text{trail-pol} \Rightarrow \text{nat literal} \Rightarrow \text{nat option nres} \rangle$ **where**
 $\langle \text{get-propagation-reason-pol} = (\lambda(-, -, -, \text{reasons}, -) L. \text{do } \{$
 $\text{ASSERT}(\text{atm-of } L < \text{length reasons});$
 $\text{let } r = \text{reasons} ! \text{atm-of } L;$
 $\text{RETURN } (\text{if } r = \text{DECISION-REASON then None else Some } r)\} \rangle$

lemma *get-propagation-reason-pol*:

$\langle (\text{uncurry } \text{get-propagation-reason-pol}, \text{uncurry } \text{get-propagation-reason}) \in$
 $[\lambda(M, L). L \in \text{lits-of-l } M]_f \text{ trail-pol } \mathcal{A} \times_r \text{Id} \rightarrow \langle \langle \text{nat-rel} \rangle \text{option-rel} \rangle \text{nres-rel} \rangle$
 $\langle \text{proof} \rangle$

definition *get-propagation-reason-raw-pol* :: $\langle \text{trail-pol} \Rightarrow \text{nat literal} \Rightarrow \text{nat nres} \rangle$ **where**
 $\langle \text{get-propagation-reason-raw-pol} = (\lambda(-, -, -, \text{reasons}, -) L. \text{do } \{$
 $\text{ASSERT}(\text{atm-of } L < \text{length reasons});$
 $\text{let } r = \text{reasons} ! \text{atm-of } L;$
 $\text{RETURN } r\} \rangle$

The version *get-propagation-reason* can return the reason, but does not have to: it can be more suitable for specification (like for the conflict minimisation, where finding the reason is not mandatory).

The following version *always* returns the reasons if there is one. Remark that both functions are linked to the same code (but *get-propagation-reason* can be called first with some additional filtering later).

definition (in $-$) *get-the-propagation-reason*
 $:: \langle ('v, 'mark) \text{ann-lits} \Rightarrow 'v \text{literal} \Rightarrow 'mark \text{option nres} \rangle$
where
 $\langle \text{get-the-propagation-reason } M L = \text{SPEC}(\lambda C.$
 $(C \neq \text{None} \longleftrightarrow \text{Propagated } L \text{ (the } C) \in \text{set } M) \wedge$
 $(C = \text{None} \longleftrightarrow \text{Decided } L \in \text{set } M \vee L \notin \text{lits-of-l } M)) \rangle$

lemma *no-dup-Decided-PropedD*:

$\langle \text{no-dup } ad \implies \text{Decided } L \in \text{set } ad \implies \text{Propagated } L \ C \in \text{set } ad \implies \text{False} \rangle$
 $\langle \text{proof} \rangle$

definition *get-the-propagation-reason-pol* :: $\langle \text{trail-pol} \Rightarrow \text{nat literal} \Rightarrow \text{nat option nres} \rangle$ **where**
 $\langle \text{get-the-propagation-reason-pol} = (\lambda(-, xs, -, \text{reasons}, -) L. \text{do } \{$
 $\text{ASSERT}(\text{atm-of } L < \text{length reasons});$

Chapter 5

LBD

LBD (literal block distance) or glue is a measure of usefulness of clauses: It is the number of different levels involved in a clause. This measure has been introduced by Glucose in 2009 (Audemart and Simon).

LBD has also another advantage, explaining why we implemented it even before working on restarts: It can speed the conflict minimisation. Indeed a literal might be redundant only if there is a literal of the same level in the conflict.

The LBD data structure is well-suited to do so: We mark every level that appears in the conflict in a hash-table like data structure.

Remark that we combine the LBD with a MTF scheme.

5.1 Types and relations

type-synonym *lbd* = $\langle \text{bool list} \rangle$

type-synonym *lbd-ref* = $\langle \text{nat list} \times \text{nat} \times \text{nat} \rangle$

Beside the actual “lookup” table, we also keep the highest level marked so far to unmark all levels faster (but we currently don’t save the LBD and have to iterate over the data structure). We also handle growing of the structure by hand instead of using a proper hash-table.

definition *lbd-ref* :: $\langle (\text{lbd-ref} \times \text{lbd}) \text{ set} \rangle$ **where**
 lbd-ref = $\{ ((\text{lbd}, \text{stamp}, m), \text{lbd}') \mid$
 $\text{length } \text{lbd}' \leq \text{Suc } (\text{Suc } (\text{uint32-max div } 2)) \wedge$
 $m = \text{length } (\text{filter id } \text{lbd}') \wedge$
 $\text{stamp} > 0 \wedge$
 $\text{length } \text{lbd} = \text{length } \text{lbd}' \wedge$
 $(\forall v \in \text{set } \text{lbd}. v \leq \text{stamp}) \wedge$
 $(\forall i < \text{length } \text{lbd}'. \text{lbd}' ! i \longleftrightarrow \text{lbd} ! i = \text{stamp})$
 $\}$

5.2 Testing if a level is marked

definition *level-in-lbd* :: $\langle \text{nat} \Rightarrow \text{lbd} \Rightarrow \text{bool} \rangle$ **where**
 level-in-lbd *i* = $(\lambda \text{lbd}. i < \text{length } \text{lbd} \wedge \text{lbd} ! i)$

definition *level-in-lbd-ref* :: $\langle \text{nat} \Rightarrow \text{lbd-ref} \Rightarrow \text{bool} \rangle$ **where**
 level-in-lbd-ref = $(\lambda i (\text{lbd}, \text{stamp}, -). i < \text{length-uint32-nat } \text{lbd} \wedge \text{lbd} ! i = \text{stamp})$

lemma *level-in-lbd-ref-level-in-lbd*:

$\langle (\text{uncurry } (\text{RETURN } \text{oo level-in-lbd-ref}), \text{uncurry } (\text{RETURN } \text{oo level-in-lbd})) \in$
 $\text{nat-rel} \times_r \text{lbd-ref} \rightarrow_f \langle \text{bool-rel} \rangle \text{nres-rel} \rangle$
 $\langle \text{proof} \rangle$

5.3 Marking more levels

definition *list-grow* **where**

$\langle \text{list-grow } xs \ n \ x = xs @ \text{replicate } (n - \text{length } xs) \ x \rangle$

definition *lbd-write* :: $\langle \text{lbd} \Rightarrow \text{nat} \Rightarrow \text{lbd} \rangle$ **where**

$\langle \text{lbd-write} = (\lambda \text{lbd } i.$

Chapter 6

Refinement of the Watched Function

There is not much to say about watch lists since they are arrays of resizable arrays, which are defined in a separate theory.

However, when replacing the elements in our watch lists from $(nat \times uint32)$ to $(nat \times uint32 \times bool)$ to enable special handling of binary clauses, we got a huge and unexpected slowdown, due to a much higher number of cache misses (roughly 3.5 times as many on a eq.atree.braun.8.unsat.cnf which also took 66s instead of 50s). While toying with the generated ML code, we found out that our version of the tuples with booleans were using 40 bytes instead of 24 previously. Just merging the *uint32* and the *bool* to a single *uint64* was sufficient to get the performance back.

Remark that however, the evaluation of terms like $(2::uint64) \wedge 32$ was not done automatically and even worse, was redone each time, leading to a complete performance blow-up (75s on my macbook for eq.atree.braun.7.unsat.cnf instead of 7s).

None of the problems appears in the LLVM code.

Chapter 7

Clauses Encoded as Positions

We use represent the conflict in two data structures close to the one used by the most SAT solvers: We keep an array that represent the clause (for efficient iteration on the clause) and a “hash-table” to efficiently test if a literal belongs to the clause.

The first data structure is simply an array to represent the clause. This theory is only about the second data structure. We refine it from the clause (seen as a multiset) in two steps:

1. First, we represent the clause as a “hash-table”, where the i -th position indicates *Some True* (respectively *Some False*, *None*) if *Pos i* is present in the clause (respectively *Neg i*, not at all). This allows to represent every not-tautological clause whose literals fits in the underlying array.
2. Then we refine it to an array of booleans indicating if the atom is present or not. This information is redundant because we already know that a literal can only appear negated compared to the trail.

The first step makes it easier to reason about the clause (since we have the full clause), while the second step should generate (slightly) more efficient code.

Most solvers also merge the underlying array with the array used to cache information for the conflict minimisation (see theory *Watched-Literals.CDCL-Conflict-Minimisation*, where we only test if atoms appear in the clause, not literals).

As far as we know, versat stops at the first refinement (stating that there is no significant overhead, which is probably true, but the second refinement is not much additional work anyhow and we don’t have to rely on the ability of the compiler to not represent the option type on booleans as a pointer, which it might be able to or not).

This is the first level of the refinement. We tried a few different definitions (including a direct one, i.e., mapping a position to the inclusion in the set) but the inductive version turned out to be the easiest one to use.

Chapter 8

Complete state

We here define the last step of our refinement: the step with all the heuristics and fully deterministic code.

After the result of benchmarking, we concluded that the use of *nat* leads to worse performance than using *sint64*. As, however, the later is not complete, we do so with a switch: as long as it fits, we use the faster (called 'bounded') version. After that we switch to the 'unbounded' version (which is still bounded by memory anyhow) if we generate Standard ML code.

We have successfully killed all natural numbers when generating LLVM. However, the LLVM binding does not have a binding to GMP integers.

8.1 Moving averages

We use (at least hopefully) the variant of EMA-14 implemented in Cadical, but with fixed-point calculation (1 is $1 \gg 32$).

Remark that the coefficient β already should not take care of the fixed-point conversion of the glue. Otherwise, *value* is wrongly updated.

type-synonym *ema* = $\langle 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \rangle$

definition *ema-bitshifting* **where**

$\langle \text{ema-bitshifting} = (1 \ll 32) \rangle$

definition (**in** $-$) *ema-update* :: $\langle \text{nat} \Rightarrow \text{ema} \Rightarrow \text{ema} \rangle$ **where**

$\langle \text{ema-update} = (\lambda \text{lbd} \text{ (value, } \alpha, \beta, \text{wait, period)}).$

$\text{let lbd} = (\text{of-nat lbd}) * \text{ema-bitshifting}$ **in**

$\text{let value} = \text{if lbd} > \text{value} \text{ then value} + (\beta * (\text{lbd} - \text{value}) \gg 32) \text{ else value} - (\beta * (\text{value} - \text{lbd}) \gg 32)$ **in**

$\text{if } \beta \leq \alpha \vee \text{wait} > 0 \text{ then (value, } \alpha, \beta, \text{wait} - 1, \text{period)}$

else

$\text{let wait} = 2 * \text{period} + 1$ **in**

$\text{let period} = \text{wait}$ **in**

$\text{let } \beta = \beta \gg 1$ **in**

$\text{let } \beta = \text{if } \beta \leq \alpha \text{ then } \alpha \text{ else } \beta$ **in**

$(\text{value}, \alpha, \beta, \text{wait}, \text{period}) \rangle$

definition (**in** $-$) *ema-init* :: $\langle 64 \text{ word} \Rightarrow \text{ema} \rangle$ **where**

$\langle \text{ema-init } \alpha = (0, \alpha, \text{ema-bitshifting}, 0, 0) \rangle$

fun *ema-reinit* **where**
 $\langle \text{ema-reinit } (value, \alpha, \beta, wait, period) = (value, \alpha, 1 \ll 32, 0, 0) \rangle$

fun *ema-get-value* :: $\langle \text{ema} \Rightarrow 64 \text{ word} \rangle$ **where**
 $\langle \text{ema-get-value } (v, -) = v \rangle$

fun *ema-extract-value* :: $\langle \text{ema} \Rightarrow 64 \text{ word} \rangle$ **where**
 $\langle \text{ema-extract-value } (v, -) = v \gg 32 \rangle$

We use the default values for Cadical: $(3::'a) / (10::'a)^2$ and $(1::'a) / (10::'a)^5$ in our fixed-point version.

abbreviation *ema-fast-init* :: *ema* **where**
 $\langle \text{ema-fast-init} \equiv \text{ema-init } (128849010) \rangle$

abbreviation *ema-slow-init* :: *ema* **where**
 $\langle \text{ema-slow-init} \equiv \text{ema-init } 429450 \rangle$

8.2 Statistics

We do some statistics on the run.

NB: the statistics are not proven correct (especially they might overflow), there are just there to look for regressions, do some comparisons (e.g., to conclude that we are propagating slower than the other solvers), or to test different option combination.

type-synonym *stats* = $\langle 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times 64 \text{ word} \times \text{ema} \rangle$

8.9 Virtual domain

The virtual domain is composed of the addressable (and accessible) elements, i.e., the domain and all the deleted clauses that are still present in the watch lists.

definition $\text{vdom-}m :: (\text{nat multiset} \Rightarrow (\text{nat literal} \Rightarrow (\text{nat} \times -) \text{ list}) \Rightarrow (\text{nat}, 'b) \text{ fmap} \Rightarrow \text{nat set})$ **where**
 $\langle \text{vdom-}m \mathcal{A} W N = \bigcup ((((' \text{ fst}) ' \text{ set} ' W ' \text{ set-mset } (\mathcal{L}_{\text{all}} \mathcal{A})) \cup \text{ set-mset } (\text{dom-}m N))$

lemma *vdom-m-simps*[*simp*]:

$$\begin{aligned} & \langle bh \in \# \text{ dom-}m \ N \implies v\text{dom-}m \ \mathcal{A} \ W \ (N(bh \hookrightarrow C)) = v\text{dom-}m \ \mathcal{A} \ W \ N \rangle \\ & \langle bh \notin \# \text{ dom-}m \ N \implies v\text{dom-}m \ \mathcal{A} \ W \ (N(bh \hookrightarrow C)) = \text{insert } bh \ (v\text{dom-}m \ \mathcal{A} \ W \ N) \rangle \\ & \langle \text{proof} \rangle \end{aligned}$$

```
lemma vdom-m-simps2[simp]:
```

$$\begin{aligned} & \langle i \in \# \text{ dom-}m \ N \implies \text{vdom-}m \ \mathcal{A} \ (W(L := W \ L @ [(i, C)])) \ N = \text{vdom-}m \ \mathcal{A} \ W \ N \rangle \\ & \langle bi \in \# \text{ dom-}m \ ax \implies \text{vdom-}m \ \mathcal{A} \ (bp(L := bp \ L @ [(bi, av')])) \ ax = \text{vdom-}m \ \mathcal{A} \ bp \ ax \rangle \\ & \langle \text{proof} \rangle \end{aligned}$$

```
lemma vdom-m-simps3[simp]:
```

$\langle \text{fst } \text{biav}' \in \# \text{ dom-}m \text{ ax} \implies \text{vdom-}m \mathcal{A} (\text{bp}(L := \text{bp } L @ [\text{biav}']) \text{ ax} = \text{vdom-}m \mathcal{A} \text{ bp ax}) \rangle$
 $\langle \text{proof} \rangle$

What is the difference with the next lemma?

lemma $[\text{simp}]$:

$\langle \text{bf} \in \# \text{ dom-}m \text{ ax} \implies \text{vdom-}m \mathcal{A} \text{ bj } (\text{ax}(\text{bf} \hookrightarrow C')) = \text{vdom-}m \mathcal{A} \text{ bj } (\text{ax}) \rangle$
 $\langle \text{proof} \rangle$

lemma $\text{vdom-}m\text{-simps}_4 [\text{simp}]$:

$\langle i \in \# \text{ dom-}m N \implies$
 $\text{vdom-}m \mathcal{A} (W (L1 := W L1 @ [(i, C1)], L2 := W L2 @ [(i, C2)])) N = \text{vdom-}m \mathcal{A} W N \rangle$
 $\langle \text{proof} \rangle$

This is $?i \in \# \text{ dom-}m ?N \implies \text{vdom-}m ?\mathcal{A} (?W(?L1.0 := ?W ?L1.0 @ [(?i, ?C1.0)], ?L2.0 := ?W ?L2.0 @ [(?i, ?C2.0)])) ?N = \text{vdom-}m ?\mathcal{A} ?W ?N$ if the assumption of distinctness is not present in the context.

lemma $\text{vdom-}m\text{-simps}_4' [\text{simp}]$:

$\langle i \in \# \text{ dom-}m N \implies$
 $\text{vdom-}m \mathcal{A} (W (L1 := W L1 @ [(i, C1), (i, C2)])) N = \text{vdom-}m \mathcal{A} W N \rangle$
 $\langle \text{proof} \rangle$

We add a spurious dependency to the parameter of the locale:

definition $\text{empty-watched} :: \langle \text{nat multiset} \Rightarrow \text{nat literal} \Rightarrow (\text{nat} \times \text{nat literal} \times \text{bool}) \text{ list} \rangle$ **where**
 $\langle \text{empty-watched } \mathcal{A} = (\lambda \cdot. []) \rangle$

lemma $\text{vdom-}m\text{-empty-watched} [\text{simp}]$:

$\langle \text{vdom-}m \mathcal{A} (\text{empty-watched } \mathcal{A}') N = \text{set-mset } (\text{dom-}m N) \rangle$
 $\langle \text{proof} \rangle$

The following rule makes the previous one not applicable. Therefore, we do not mark this lemma as simp.

lemma $\text{vdom-}m\text{-simps}_5$:

$\langle i \notin \# \text{ dom-}m N \implies \text{vdom-}m \mathcal{A} W (\text{fmupd } i \text{ } C \text{ } N) = \text{insert } i (\text{vdom-}m \mathcal{A} W N) \rangle$
 $\langle \text{proof} \rangle$

lemma $\text{in-watch-list-in-vdom}$:

assumes $\langle L \in \# \mathcal{L}_{\text{all}} \mathcal{A} \rangle$ **and** $\langle w < \text{length } (\text{watched-by } S \text{ } L) \rangle$
shows $\langle \text{fst } (\text{watched-by } S \text{ } L ! w) \in \text{vdom-}m \mathcal{A} (\text{get-watched-wl } S) (\text{get-clauses-wl } S) \rangle$
 $\langle \text{proof} \rangle$

lemma $\text{in-watch-list-in-vdom}'$:

assumes $\langle L \in \# \mathcal{L}_{\text{all}} \mathcal{A} \rangle$ **and** $\langle A \in \text{set } (\text{watched-by } S \text{ } L) \rangle$
shows $\langle \text{fst } A \in \text{vdom-}m \mathcal{A} (\text{get-watched-wl } S) (\text{get-clauses-wl } S) \rangle$
 $\langle \text{proof} \rangle$

lemma $\text{in-dom-in-vdom} [\text{simp}]$:

$\langle x \in \# \text{ dom-}m N \implies x \in \text{vdom-}m \mathcal{A} W N \rangle$
 $\langle \text{proof} \rangle$

lemma $\text{in-vdom-}m\text{-upd}$:

$\langle x1f \in \text{vdom-}m \mathcal{A} (g(x1e := (g \text{ } x1e)[x2 := (x1f, x2f)])) \text{ } b \rangle$
if $\langle x2 < \text{length } (g \text{ } x1e) \rangle$ **and** $\langle x1e \in \# \mathcal{L}_{\text{all}} \mathcal{A} \rangle$
 $\langle \text{proof} \rangle$

lemma *in-vdom-m-fmdropD*:

$\langle x \in \text{vdom-m } \mathcal{A} \text{ ga } (\text{fmdrop } C \text{ baa}) \implies x \in (\text{vdom-m } \mathcal{A} \text{ ga } \text{baa}) \rangle$
 $\langle \text{proof} \rangle$

definition *cach-refinement-empty* **where**

$\langle \text{cach-refinement-empty } \mathcal{A} \text{ cach} \longleftrightarrow$
 $(\text{cach}, \lambda-. \text{SEEN-UNKNOWN}) \in \text{cach-refinement } \mathcal{A} \rangle$

Chapter 12

Printing information about progress

We provide a function to print some information about the state. This is mostly meant to ease extracting statistics and printing information during the run. Remark that this function is basically an FFI (to follow Andreas Lochbihler words) and is not unsafe (since printing has not side effects), but we do not need any correctness theorems.

However, it seems that the PolyML as targeted by *export-code checking* does not support that print function. Therefore, we cannot provide the code printing equations by default.

For the LLVM version code equations are not supported and hence we replace the function by hand.

Chapter 13

Rephasing

We implement the idea in CaDiCaL of rephasing:

- We remember the best model found so far. It is used as base.
- We flip the phase saving heuristics between *True*, *False*, and random.

definition *rephase-init* :: $\langle \text{bool} \Rightarrow \text{bool list} \Rightarrow \text{bool list nres} \rangle$ **where**

```
rephase-init b  $\varphi$  = do {  
  let n = length  $\varphi$ ;  
  nfoldli [0.. $n$ ]  
    ( $\lambda$ -. True)  
    ( $\lambda$  a  $\varphi$ . do {  
      ASSERT( $a < \text{length } \varphi$ );  
      RETURN ( $\varphi[a := b]$ )  
    })  
   $\varphi$   
}
```

lemma *rephase-init-spec*:

```
 $\langle \text{rephase-init } b \varphi \leq \text{SPEC}(\lambda \psi. \text{length } \psi = \text{length } \varphi) \rangle$   
proof
```

definition *copy-phase* :: $\langle \text{bool list} \Rightarrow \text{bool list} \Rightarrow \text{bool list nres} \rangle$ **where**

```
copy-phase  $\varphi$   $\varphi'$  = do {  
  ASSERT(length  $\varphi$  = length  $\varphi'$ );  
  let n = length  $\varphi'$ ;  
  nfoldli [0.. $n$ ]  
    ( $\lambda$ -. True)  
    ( $\lambda$  a  $\varphi'$ . do {  
      ASSERT( $a < \text{length } \varphi$ );  
      ASSERT( $a < \text{length } \varphi'$ );  
      RETURN ( $\varphi'[a := \varphi[a]$ )

lemma *bitXOR-1-if-mod-2-int*: $\langle \text{bitOR } L \ 1 = (\text{if } L \bmod 2 = 0 \text{ then } L + 1 \text{ else } L) \rangle$ **for** $L :: \text{int}$
 $\langle \text{proof} \rangle$

lemma *bitOR-1-if-mod-2-nat*:
 $\langle \text{bitOR } L \ 1 = (\text{if } L \bmod 2 = 0 \text{ then } L + 1 \text{ else } L) \rangle$
 $\langle \text{bitOR } L \ (\text{Suc } 0) = (\text{if } L \bmod 2 = 0 \text{ then } L + 1 \text{ else } L) \rangle$ **for** $L :: \text{nat}$
 $\langle \text{proof} \rangle$

15.1 Code for the initialisation of the Data Structure

The initialisation is done in three different steps:

1. First, we extract all the atoms that appear in the problem and initialise the state with empty values. This part is called *initialisation* below.
2. Then, we go over all clauses and insert them in our memory module. We call this phase *parsing*.
3. Finally, we calculate the watch list.

Splitting the second from the third step makes it easier to add preprocessing and more important to add a bounded mode.

15.1.1 Initialisation of the state

definition (**in** $-$) *atoms-hash-empty* **where**
 $[\text{simp}]: \langle \text{atoms-hash-empty} - = \{\} \rangle$

 $\langle \text{proof} \rangle$

lemma *isa-vmtf-init-cong*:

$\langle \text{set-mset } \mathcal{A} = \text{set-mset } \mathcal{B} \implies L \in \text{isa-vmtf-init } \mathcal{A} M \implies L \in \text{isa-vmtf-init } \mathcal{B} M \rangle$
 $\langle \text{proof} \rangle$

type-synonym (in $-$) *twl-st-wl-heur-init* =

$\langle \text{trail-pol} \times \text{arena} \times \text{conflict-option-rel} \times \text{nat} \times$
 $(\text{nat} \times \text{nat literal} \times \text{bool}) \text{ list list} \times \text{isa-vmtf-remove-int-option-fst-As} \times \text{bool list} \times$
 $\text{nat} \times \text{conflict-min-cach-l} \times \text{lbd} \times \text{vdom} \times \text{bool} \rangle$

type-synonym (in $-$) *twl-st-wl-heur-init-full* =

$\langle \text{trail-pol} \times \text{arena} \times \text{conflict-option-rel} \times \text{nat} \times$
 $(\text{nat} \times \text{nat literal} \times \text{bool}) \text{ list list} \times \text{isa-vmtf-remove-int-option-fst-As} \times \text{bool list} \times$
 $\text{nat} \times \text{conflict-min-cach-l} \times \text{lbd} \times \text{vdom} \times \text{bool} \rangle$

The initialisation relation is stricter in the sense that it already includes the relation of atom inclusion.

Remark that we replace $D = \text{None} \longrightarrow j \leq \text{length } M$ by $j \leq \text{length } M$: this simplifies the proofs and does not make a difference in the generated code, since there are no conflict analysis at that level anyway.

KILL duplicates below, but difference: vmtf vs vmtf_init watch list vs no WL OC vs non-OC

Chapter 19

Restarts

lemma *twl-st-heur-change-subsumed-clauses*:

assumes $\langle (M', N', D', j, W', vm, clvs, cach, lbd, outl, stats, heur, vdom, avdom, lcount, opts, old-arena), (M, N, D, NE, UE, NS, US, Q, W) \rangle \in twl-st-heur$
 $\langle set-mset (all-atms N ((NE+UE)+(NS+US))) = set-mset (all-atms N ((NE+UE)+(NS'+US')) \rangle$
shows $\langle (M', N', D', j, W', vm, clvs, cach, lbd, outl, stats, heur, vdom, avdom, lcount, opts, old-arena), (M, N, D, NE, UE, NS', US', Q, W) \rangle \in twl-st-heur$
 $\langle proof \rangle$

This is a list of comments (how does it work for glucose and cadical) to prepare the future refinement:

1. Reduction

- every 2000+300*n (roughly since inprocessing changes the real number, cadical) (split over initialisation file); don't restart if level < 2 or if the level is less than the fast average
- $curRestart * nbclausesbeforereduce$; $curRestart = (conflicts / nbclausesbeforereduce) + 1$ (glucose)

2. Killed

- half of the clauses that **can** be deleted (i.e., not used since last restart), not strictly LBD, but a probability of being useful.
- half of the clauses

3. Restarts:

- EMA-14, aka restart if enough clauses and $slow_glue_avg * opts.restartmargin > fast_glue$ (file ema.cpp)
- $(lbdQueue.getavg() * K) > (sumLBD / conflictsRestarts)$, $conflictsRestarts > LOWER-BOUND-FO$ && $lbdQueue.isvalid() \ \&\& \ trail.size() > R * trailQueue.getavg()$

global-interpretation *twl-restart id*
 $\langle \text{proof} \rangle$

We first fix the function that proves termination. We don't take the "smallest" function possible (other possibilities that are growing slower include $\lambda n. n \gg 50$). Remark that this scheme is not compatible with Luby (TODO: use Luby restart scheme every once in a while like Crypto-Minisat?)

Chapter 21

Full IsaSAT

We now combine all the previous definitions to prove correctness of the complete SAT solver:

1. We initialise the arena part of the state;
2. Then depending on the options and the number of clauses, we either use the bounded version or the unbounded version. Once have if decided which one, we initiale the watch lists;
3. After that, we can run the CDCL part of the SAT solver;
4. Finally, we extract the trail from the state.

Remark that the statistics and the options are unchecked: the number of propagations might overflows (but they do not impact the correctness of the whole solver). Similar restriction applies on the options: setting the options might not do what you expect to happen, but the result will still be correct.

21.1 Correctness Relation

We cannot use *cdcl-twl-stgy-restart* since we do not always end in a final state for *cdcl-twl-stgy*.

definition *conclusive-TWL-run* :: $\langle 'v \text{ twl-st} \Rightarrow 'v \text{ twl-st nres} \rangle$ **where**

$\langle \text{conclusive-TWL-run } S =$
 $\text{SPEC}(\lambda T. \exists n \ n'. \text{cdcl-twl-stgy-restart-with-leftovers}^{**} (S, n) (T, n') \wedge \text{final-twl-state } T) \rangle$

definition *conclusive-TWL-run-bounded* :: $\langle 'v \text{ twl-st} \Rightarrow (\text{bool} \times 'v \text{ twl-st}) \text{ nres} \rangle$ **where**

$\langle \text{conclusive-TWL-run-bounded } S =$
 $\text{SPEC}(\lambda(\text{brk}, T). \exists n \ n'. \text{cdcl-twl-stgy-restart-with-leftovers}^{**} (S, n) (T, n') \wedge$
 $(\text{brk} \longrightarrow \text{final-twl-state } T)) \rangle$

To get a full CDCL run:

- either we fully apply *cdcl_W-restart-mset.cdcl_W-stgy* (up to restarts)
- or we can stop early.

definition *conclusive-CDCL-run* **where**

$\langle \text{conclusive-CDCL-run } CS \ T \ U \longleftrightarrow$
 $(\exists n \ n'. \text{cdcl}_W\text{-restart-mset.cdcl}_W\text{-restart-stgy}^{**} (T, n) (U, n') \wedge$

381

The calling convention of LLVM and clang is not the same, so returning the model is currently unsupported. We return only the flags (as ints, not as bools) and the statistics.

The setup to transmit the version is a bit complicated, because it LLVM does not support direct export of string literals. Therefore, we actually convert the version to an array chars (more precisely, of machine words – ended with 0) that can be read and printed by the C layer. Note the conversion must be automatic, because the version depends on the underlying git repository.

function *array-of-version where*

$\langle \text{array-of-version } i \text{ str arr} =$
 $(\text{if } i \geq \text{length str then arr}$
 $\text{else array-of-version } (i+1) \text{ str } (\text{arr}[i := \text{str } ! i])) \rangle$
