Abstract

Abstract—Generating and checking proof certificates is important to increase the trust in automated reasoning tools. In recent years formal verification using computer algebra became more important and is heavily used in automated circuit verification. An existing proof format which covers algebraic reasoning and allows efficient proof checking is the practical algebraic calculus. In this development, we present the verified checker Pastèque that is obtained by synthesis via the Refinement Framework.

This is the formalization going with our FMCAD'20 tool presentation [1].

1   Duplicate Free Multisets

Duplicate free multisets are isomorphic to finite sets, but it can be useful to reason about duplication to speak about intermediate execution steps in the refinements.

3.2 PAC Format

The PAC format contains three kind of steps:

- add that adds up two polynomials that are known.

- mult that multiply a known polynomial with another one.

- del that removes a polynomial that cannot be reused anymore.

To model the simplification that happens, we add the $p - p' \in$ *polynom-bool* stating that p and p' are equivalent.

type-synonym *pac-st* = ‹(nat set × int-poly multiset)›

inductive *PAC-Format* :: ‹pac-st ⇒ pac-st ⇒ bool› **where**
add:
  ‹PAC-Format (𝒱, A) (𝒱, add-mset p' A)›
if
  ‹p ∈# A› ‹q ∈# A›
  ‹p+q − p' ∈ ideal polynom-bool›
  ‹vars p' ⊆ 𝒱› |
mult:
  ‹PAC-Format (𝒱, A) (𝒱, add-mset p' A)›
if
  ‹p ∈# A›
  ‹p∗q − p' ∈ ideal polynom-bool›
  ‹vars p' ⊆ 𝒱›
  ‹vars q ⊆ 𝒱› |
del:
  ‹p ∈# A ⟹ PAC-Format (𝒱, A) (𝒱, A − {#p#})› |
extend-pos:
  ‹PAC-Format (𝒱, A) (𝒱 ∪ {x' ∈ vars (− Var x + p'). x' ∉ 𝒱}, add-mset (− Var x + p') A)›
  if
    ‹(p')² − p' ∈ ideal polynom-bool›
    ‹vars p' ⊆ 𝒱›
    ‹x ∉ 𝒱›

In the PAC format above, we have a technical condition on the normalisation: *vars* $p' \subseteq$ *vars* $(p + q)$ is here to ensure that we don't normalise *0* to $(Var\ x)^2 - Var\ x$ for a new variable x. This is completely obvious for the normalisation processe we have in mind when we write the specification, but we must add it explicitly because we are too general.

lemmas *PAC-Format-induct-split* =
  PAC-Format.induct[split-format(complete), *of* V A V' A' **for** V A V' A']

lemma *PAC-Format-induct*[consumes 1, case-names add mult del ext]:

4.2 Finite map and multisets

Roughly the same as *ran* and *dom*, but with duplication in the content (unlike their finite sets counterpart) while still working on finite domains (unlike a function mapping). Remark that *dom-m* (the keys) does not contain duplicates, but we keep for symmetry (and for easier use of multiset operators as in the definition of *ran-m*).

7 Polynomials of strings

Isabelle's definition of polynomials only work with variables of type *nat*. Therefore, we introduce
a version that uses strings.

7.1 Polynomials and Variables

lemma *poly-embed-EX*:
  ‹∃ φ. *bij* (φ :: *string* ⇒ *nat*)›
  by (*rule countableE-infinite*[*of* ‹*UNIV* :: *string set*›])
      (*auto intro*!: *infinite-UNIV-listI*)

Using a multiset instead of a list has some advantage from an abstract point of view. First, we
can have monomials that appear several times and the coefficient can also be zero. Basically,
we can represent un-normalised polynomials, which is very useful to talk about intermediate
states in our program.

type-synonym *term-poly* = ‹*string multiset*›

9   Polynomialss as Lists

9.1   Addition

In this section, we refine the polynomials to list. These lists will be used in our checker to represent the polynomials and execute operations.

There is one *key* difference between the list representation and the usual representation: in the former, coefficients can be zero and monomials can appear several times. This makes it easier to reason on intermediate representation where this has not yet been sanitized.

fun *add-poly-l′* :: ⟨*llist-polynom* × *llist-polynom* ⇒ *llist-polynom*⟩ **where**

10 Executable Checker

In this layer we finally refine the checker to executable code.

10.1 Definitions

Compared to the previous layer, we add an error message when an error is discovered. We do not attempt to prove anything on the error message (neither that there really is an error, nor that the error message is correct).

Extended error message   **datatype** $'a$ *code-status* =
  is-cfailed: *CFAILED* (*the-error*: $'a$) |
  CSUCCESS |
  is-cfound: *CFOUND*

In the following function, we merge errors. We will never merge an error message with an another error message; hence we do not attempt to concatenate error messages.

fun *merge-cstatus* **where**
  ‹*merge-cstatus* (*CFAILED a*) - = *CFAILED a*› |
  ‹*merge-cstatus* - (*CFAILED a*) = *CFAILED a*› |
  ‹*merge-cstatus CFOUND* - = *CFOUND*› |
  ‹*merge-cstatus* - *CFOUND* = *CFOUND*› |
  ‹*merge-cstatus* - - = *CSUCCESS*›

definition *code-status-status-rel* :: ‹($'a$ *code-status* × *status*) *set*› **where**
‹*code-status-status-rel* =
  {(*CFOUND*, *FOUND*), (*CSUCCESS*, *SUCCESS*)} ∪
  {(*CFAILED a*, *FAILED*)| *a*. *True*}›

lemma *in-code-status-status-rel-iff* [*simp*]:
  ‹(*CFOUND*, *b*) ∈ *code-status-status-rel* ⟷ *b* = *FOUND*›
  ‹(*a*, *FOUND*) ∈ *code-status-status-rel* ⟷ *a* = *CFOUND*›
  ‹(*CSUCCESS*, *b*) ∈ *code-status-status-rel* ⟷ *b* = *SUCCESS*›
  ‹(*a*, *SUCCESS*) ∈ *code-status-status-rel* ⟷ *a* = *CSUCCESS*›

This is a hack for performance. There is no need to recheck that that a char is valid when working on chars coming from strings... It is not that important in most cases, but in our case the preformance difference is really large.

definition *unsafe-asciis-of-literal* :: ‹-› **where**
  ‹*unsafe-asciis-of-literal xs* = *String.asciis-of-literal xs*›

definition *unsafe-asciis-of-literal′* :: ‹-› **where**

[*simp, symmetric, code*]: ‹*unsafe-asciis-of-literal′ = unsafe-asciis-of-literal*›

code-printing
  constant *unsafe-asciis-of-literal′* ⇀
    (*SML*) !(*List.map* (*fn c => let val k = Char.ord c in IntInf.fromInt k end*) */o String.explode*)

Now comes the big and ugly and unsafe hack.

Basically, we try to avoid the conversion to IntInf when calculating the hash. The performance gain is roughly 40%, which is a LOT and definitively something we need to do. We are aware that the SML semantic encourages compilers to optimise conversions, but this does not happen here, corroborating our early observation on the verified SAT solver IsaSAT.x

Below is the full correctness theorems. It basically states that:

1. assuming that the input polynomials have no duplicate variables

Then:

1. if the checker returns *CFOUND*, the spec is in the ideal and the PAC file is correct

2. if the checker returns *CSUCCESS*, the PAC file is correct (but there is no information on the spec, aka checking failed)

3. if the checker return *CFAILED err*, then checking failed (and *err might* give you an indication of the error, but the correctness theorem does not say anything about that).

   The input parameters are:

4. the specification polynomial represented as a list

5. the input polynomials as hash map (as an array of option polynom)

6. a represention of the PAC proofs.

  by *auto*

It would be more efficient to move the parsing to Isabelle, as this would be more memory efficient (and also reduce the TCB). But now comes the fun part: It cannot work. A stream (of a file) is consumed by side effects. Assume that this would work. The code could look like:

Let (*read-file file*) *f*

This code is equal to (in the HOL sense of equality): *let - = read-file file in Let* (*read-file file*) *f*

However, as an hypothetical *read-file* changes the underlying stream, we would get the next token. Remark that this is already a weird point of ML compilers. Anyway, I see currently two solutions to this problem:

1. The meta-argument: use it only in the Refinement Framework in a setup where copies are disallowed. Basically, this works because we can express the non-duplication constraints on the type level. However, we cannot forbid people from expressing things directly at the HOL level.

2. On the target language side, model the stream as the stream and the position. Reading takes two arguments. First, the position to read. Second, the stream (and the current

position) to read. If the position to read does not match the current position, return an error. This would fit the correctness theorem of the code generation (roughly "if it terminates without exception, the answer is the same"), but it is still unsatisfactory.

end

definition $\varphi :: \langle string \Rightarrow nat \rangle$ **where**
 $\langle \varphi = (SOME\ \varphi.\ bij\ \varphi) \rangle$

lemma *bij-φ*: $\langle bij\ \varphi \rangle$
  using *someI*$[of\ \langle\ \lambda\varphi :: string \Rightarrow nat.\ bij\ \varphi\rangle]$
  unfolding φ*-def*$[symmetric]$
  using *poly-embed-EX*
